Mononucleosis (Mono)

What is Mononucleosis?
Mononucleosis is a contagious disease usually caused by the Epstein-Barr virus (EBV), which is a member of the herpesvirus family, and affects certain blood cells. Mononucleosis usually occurs in adolescents and young adults. In young children the disease is generally mild and more difficult to recognize.

What are the symptoms?
• Sore throat
• Loss of appetite
• Headaches
• Fever
• Swollen glands
• Feeling unusually tired much of the time
• Sometimes a swollen spleen or liver

Symptoms usually appear 4 to 6 weeks after exposure and may last several weeks. Following recovery, 15-20% of those who become ill may carry the virus in their nose and throat for a prolonged period of time.

How is it spread?
Mononucleosis is spread person-to-person by contact with the saliva of an infected person. Exposure usually occurs by kissing mouth to mouth, but the virus can be spread from items contaminated with saliva, for example: hands, toys, drinking glasses and bottles, eating utensils, food and cigarettes.

How is it diagnosed?
Healthcare providers typically diagnose the illness based on symptoms. Laboratory tests are not usually needed to diagnose infectious mononucleosis. However, specific blood tests may be needed to identify the cause of illness in people who do not have a typical case of this illness.

How is it treated?
There is no specific treatment for this virus.
• Treat fevers with non-aspirin products (acetaminophen, ibuprofen).
• Get plenty of rest.
• Drink plenty of fluids such as water, fruit juice and tea.
• Avoid contact sports; the spleen often enlarges and may rupture if it is hit hard.

How is Mononucleosis prevented?
• Avoid all oral contact (kissing, sharing drinking containers, or using the same eating utensils) with individuals that have the symptoms of, or have recently had Mononucleosis.
• Wash hands thoroughly throughout the day and especially after contact with saliva.
